Meeting 2 – Client Requirement Meeting

Date: 28 October 2026
Members: Mahesh and Adrina

Paris Under Pressure – Client Meeting Notes

1. User Groups

Three main user groups were discussed:

- People getting injured.
- Healthcare-sector IT staff responsible for dispatching ambulances.
- Ambulance staff.

Medical Records

- Ambulance staff could potentially access a person's medical history.
- Medical records could help responders understand previous medical conditions.
- Access would depend on the availability of medical records.

National ID

- A person's national ID could be used to identify their medical records.
- Medical history may include previous conditions such as heart attacks or diabetes.

2. Shopkeeper Verification

Question: How can we confirm that a shopkeeper really owns the shop?

- Businesses are registered with the government.
- Registered businesses have a business registration number.
- Shopkeepers could provide their business registration number during registration.
- Insurance services were also mentioned in connection with shop-related issues.

3. Estimated Financial Loss

Question: Should the estimated loss be an exact amount or a range?

- Shopkeepers could provide a monetary amount for the damage.
- Supporting proof of the damage would be important.
- Insurance companies have different coverage limits.
- The amount claimed may depend on the business's insurance coverage.

4. Repeated Incidents

Question: What makes an area repeated?

- The question was raised during the discussion.
- No clear answer was provided in this recording.

5. Duplicate Reports

Question: How can we identify duplicate reports?

- The discussion considered two situations:
    - One person submitting multiple reports.
    - Two people reporting the same incident.
- Users should not be blocked from submitting multiple reports.
- A person may experience or witness different incidents.
- A person could report building damage and then report an injured person.
- Both reports should be allowed.

1. Multiple People Reporting the Same Incident

- Two people may report the same incident.
- Different reporters may provide different amounts of information.
- One person might report that someone was shot.
- Another person who knows the injured person might provide more medical details.

2. Combining Reports

- Information from different reports could be combined.
- Instead of showing two separate entries, the dashboard could display one detailed incident entry.
- Combining reports could provide more information about the injured person.

3. Registration Using National ID

- Users were described as registering with their national identity card number.
- The national ID could help identify the person submitting the report.

4. Reporting an Injury on Behalf of Someone Else

- The reporter may not know the injured person's national ID.
- The reporter may not know the injured person's name.
- The reporter may not know their phone number.
- This could make identifying the injured person difficult.

5. Mandatory Reporting Fields

- Some information could be mandatory when submitting a report.
- The reporting form should not contain too many questions.
- The system should balance collecting useful information with making reporting easy.

6. Location Matching

- Location was suggested as a way to identify related reports.
- Reports submitted from the same location could be compared.
- Location could help narrow down duplicate reports.

7. Photographs

- Pictures could help identify whether reports relate to the same incident.
- Photographs were discussed alongside location information.

8. Incident Clusters

- Several reports could come from the same area.
- Reports from the same location could be grouped into a cluster.
- A cluster could be displayed as one incident on the government dashboard.

9. Device Location Data

- Location data from devices with the application installed could be used.
- Device information could provide additional details about an incident.

10. Fall Detection

- Phones or wearable devices could potentially detect falls.
- Device sensors could detect changes in position or movement.
- A fall-detection signal could potentially be sent to the system.

11. Combining Multiple Data Sources

- Device signals could be combined with reports submitted by other people.
- Multiple data points could help identify a particular incident.

6. User Groups and Dashboard Access

- Three main user groups were discussed.
- Two user groups were described as having dashboard or administrative access.
- Government or healthcare officials and ambulance staff were discussed as users with additional permissions.

7. Marking Incidents as Resolved

- Government or healthcare officials could mark incidents as resolved.
- Ambulance staff could also mark incidents as resolved.
- People reporting their own injuries should not be allowed to mark their cases as resolved.
- This restriction was suggested to prevent misuse.
- Staff could provide reasons when marking an incident as resolved.

8. Account Approval

Question: Who approves responder and official accounts?

- Government IT desk staff were suggested as the account approvers.
- Government IT officers would initially have administrative access.
- They could decide whether to grant access to other users.

9. Default User Access

- Newly registered users would be considered guest users by default.
- Additional permissions would need to be granted by authorised government staff.

10. Web-Based or Mobile Application

Question: Should the application be web-based or mobile?

- The decision was left to the development team.
- Both web-based and mobile applications were discussed.
- A website could be accessed through a laptop or browser.
- A mobile application could offer greater access to device features.

Mobile Application Features

- Mobile applications could access device cameras.
- Mobile applications could use motion detection.
- Mobile applications could access device sensors.
- These features were discussed as advantages of a mobile application.

Web Application Features

- Web applications could provide access through browsers.
- A map API could be used to handle location-related features.
- Direct location signals from a device were not described as essential.

11. Language Preferences

Question: Which languages should the application support?

- French was initially suggested.
- English was also suggested to accommodate foreigners.
- French and English were discussed as suitable language options.

12. Measuring Application Success

Question: How will we know if the application made things better?

- The number of resolved cases was suggested as a measure of success.
- The system could measure how many cases are resolved within a given period.
- A higher number of resolved cases within a period was described as a positive result.

Response Efficiency

- The application should help reduce the gap between people needing healthcare support and receiving assistance.
- The speed at which healthcare services can support injured people was highlighted.
- Improving this measure was described as an important goal of the application.

Important points highlighted from the meeting

1. **User accounts and permissions**

- Three main user groups were discussed: people reporting injuries, healthcare IT/dispatch staff and ambulance staff.
- New registrations should initially receive guest-level access.
- Government IT staff should approve elevated permissions.
- Officials and ambulance responders can mark cases as resolved.
- A reason could be recorded when closing a case.

2. **Injury reporting**

- Users may be asked for a national identification number during registration.
- Reports should have enough information to identify incidents.
- Reporting forms should avoid too many mandatory questions.
- Medical history access was mentioned as a potential enhancement.
- Injury severity levels still need to be clarified.

3. **Shop vandalism**

- Business registration numbers can help verify shops.
- Shopkeepers may provide estimated financial losses.
- Supporting evidence should be provided where possible.
- Insurance coverage and claim limits were discussed.

4. **Duplicate reporting**

- Users should not be blocked from reporting multiple incidents.
- Different people may provide different details about the same incident.
- Location can help identify possible duplicates.
- Similar reports could be combined into one detailed incident record.
- Photographs, timing and potentially device signals were mentioned as additional information that might help.

5. **Platform and success measurement**

- The team can decide between mobile and web.
- A mobile app may offer more device integration.
- A web application provides convenient browser access.
- French and English were suggested.
- Resolved case counts and response speed were highlighted as measures of success.

Questions that still need clarification

1. What are the exact injury severity categories?
2. Who can access sensitive medical records?
3. How many incidents make an area a hotspot?
4. Who determines whether a report is false?
5. Should duplicate reports merge automatically or after official review?
6. Is a national ID mandatory for all users, including visitors?
7. Should damage loss be entered as an exact amount, range or both?
